Rexx LA meeting

IBM Laboratories, Boeblingen

May 2004

Purpose of this Tutorial

- Intended for Classic Rexx and/or IBM Object Rexx users

- With a working REXX knowledge

- And the Need/Desire to quickly learn NetRexx basics

- Based on the language differences

From classic Rexx to NetRexx

- Same/Similar language constructs
- But with subtile differences
- Both in Semantics
- … and Syntax (Notation)
- We Focus on the differences now

Notation of String Literals

- Backslash(\) used as an ESCAPE-character
- Rexx Literal „C:\tutor\Tutorial.PTT"
- Must be denoted as
  „C:\\tutor\\Tutorial.PPT"
- Attention: special escape sequences!!

Escape Sequences in String Literals

- \t Tabulation (tab)
- \n new-line (line-feed)
- \r return (carriage return)
- \f formfeed
- \" double quote
- \' single quote

- \0 null character
- \xhh hexadecimal character defined by hex digits (hh)
- \uhhhh unicode character defined by hex digits (hhhh)
- \\ represents single backslash !

Notation of Hexadecimal and Binary Literals

- ‚0123456789ABCDEF'x   in Rexx
- Is: 16x'0123456789ABCDEF' in NetRexx
- ‚01000100'b in Rexx
- Is: 8b'01000100' in NetRexx

- Both upper/lowercase x/b allowed
- Length 0 may be used (literal length counts)

Notation of Variable Names

- As usual in Programming languages, but
  - NO exclamation points (!) allowed in Variable names
  - NO question marks (?) allowed in variable names
  - In general: NO special characters (except ‚$' and underline „_")
  - So why we did allow them in the first place ?

Notation of Stems

- ***Rexx*** notation is ***abc.def***
- ***Object Rexx*** notation is ***abc.def***
- ***OR*** abc[def]
- ***NetRexx*** notation is ***ONLY abc[def]***
- And ***Stem*** must be defined as a ***Rexx*** Variable before first usage, i.e.

  abc = Rexx <default value>

Notation of Stems (2)

- With multiple Indices:
- Rexx notation is abc.x.y.z
- Object Rexx notation is abc.x.y.z
- OR abc[x,y,z]
- NetRexx notation is ONLY abc[x,y,z]
- And each Stem must be *defined as a Rexx Variable* before first usage, i.e.
- abc = Rexx <default value>

Notation of Stems (3)

- Stems are now called ‚Indexed Strings' in NetRexx

- Wrong, wrong, Mike

- Better we would be able to define a Stem as
  - X = RexxStem ‚'
  - Or Y=Stem ‚'   etc

- in NetRexx, you never know from the ‚first Declaration' whether a Variable (Property) is a (Rexx) Stem or a (Rexx) String !! (it's a pity)

Attention (NetRexx specifics)

- X = Rexx ,'
- May be
  - a simple ,Rexx' ,String' (to be able to use the NetRexx String functions (like length, index, pos, lastpos, etc, etc)
  - A Word-List (to be able to use words(), wordpos(), etc)
  - A ,classic Rexx' Stem
  - A ,Rexx' Decimal Number
  - or each/any of that.
- But you cannot see from the NOTATION which variation is used.!

Using Functions vs. Methods (in Object Oriented Languages)

- It's a PITY !

- When I do have a simple (Java) String, I can NOT use the ‚Rexx' WORDS or WORDPOS functions, for instance, directly, on this String.

- I will have to declare/convert it to a REXX String before – anyway, you may use Rexx(String)!

- Correct ??

- So why *cannot we use Functions here* (which will be applicable to all cases) ? Sorry, but why?

- Same notation for INDEXED ARRAYS and INDEXED Strings (formerly called ‚Stems') in NetRexx, i.e.

- abc[x,y,z]

- may be
  - A NetRexx Indexed String (Stem) reference   OR
  - A NetRexx/Java Array reference !
  - depending on initial ‚TYPE' Definition

- Object REXX Array Indices start with 1
- but NetRexx/Java Indices start with 0
  - hence abc[1] is the FIRST element in Object Rexx
  - But abc[1] is the SECOND Element in NetRexx or Java
  - This difference applies ONLY to ARRAYS, NOT to Stems !!

CONTINUATION character

- CONTINUATION character
  - is a trailing COMMA (,) in classic Rexx and Object Rexx
  - But is a trailing HYPHEN (-) in NetRexx
- Advantage / pitfall ??
- Why do we need it at all (except for ,abut') ???
- Rey Rule (1): If a line *ends* with an OPERATOR, the next line is a continuation.
- Rey Rule (2): If a line *starts* with an OPERATOR (like +,-,*,/,&,|,\, etc,etc) it *MUST BE a continuation*!
- Or what ?

NOTES (inline comments)

- Concept of NOTES was always missing in Rexx!
- A ‚Note' is a COMMENT at the end of the line
  - Must be written as /* my note */ in classic Rexx
  - Object Rexx and NetRexx use the double hyphen (--) to introduce a NOTE (as in SQL)
  - Note that Java uses ‚//' to introduce a Note (and ‚--' as the decrement operator (which means REMAINDER in REXX !!))
  - A NOTE is always finished on the same line !

- … By the rivers of BABYLON !!

Operators

- Same set of operators in NetRexx than in classic Rexx!

- But COMPARISON of Text strings is CASE-BLIND by default !!
  - Hence ‚abc' = ‚ABC' in NetRexx !!
  - Must use ‚strict comparison' in NetRexx when needing CASE-sensitive Comparison.
  - Probably more natural than original REXX definition !
  - Good choice for a change, Mike!

Concept of TYPES

- ‚classic REXX' and OBJECT REXX are essentially TYPE-LESS languages!
- NetRexx (and Java) use/need STRICT TYPING
- NetRexx uses type ‚Rexx' as default (and type Rexx is essentially TYPE-LESS again in NetRexx!)
- But NetRexx Type ‚Rexx' is overloaded with too many different semantical meanings (Rexx String, Rexx Indexed String (Stem), Rexx WordList, Rexx (Decimal) Number, etc, etc)

Standard (Primitive) TYPES

- Boolean   (0/1)
- Byte   (0,1,2,3,4,5,6,7)
- Short   (half word SIGNED integer)
- Int   (full word SIGNED integer)
- Long   (double word SIGNED integer)
- Float   (full word SIGNED Real Number)
- Double   (double word SIGNED Real Number)
- Char   (is a UNICODE Character in NetRexx/Java)
- Primitive Types identical to Java!

Dimensioned TYPES

- Any Variable may be DIMENSIONED
- Use square BRACKETS (,[, and ,]') to define dimensions
- X = int[3,5]
- Y = char[17]
- But NOTE that first ELEMENT has Index 0 and NOT 1 !!! (ill designed by Java!!)
- Difficult to distinguish Stems and Arrays!

Dimensioned TYPES

- Any Variable may be DIMENSIONED
- Use square BRACKETS (,[, and ,]') to define dimensions
- X = int[3,5]
- Y = char[17]
- But NOTE that first ELEMENT has Index 0 and NOT 1 !!! (ill designed by Java!!)

Dimensioned TYPES (2)

- Empty Index bounds are acceptible
- Similar to the concept of ‚adjustable‘ arrays in other languages
- Hence the following declarations are OK
  - X = int[,,]
  - Y = char[]
  - Z = Rexx[]

Initial (default) Values

- NetRexx uses the EQUAL Sign for TYPE definitions
- Hence syntax is
  - name = <type> [<dimensions>] <default value>
- Probably using the colon instead of the equal sign would have been a BETTER decision !!!

… WHY ?

- With the current NetRexx notation you NEVER know whether a clause is an assignment or a type definition!
- Would also correspond more naturally to languages as Pascal or UML (Unified modelling language)
- item_no = Rexx 0 /*Stem!*/
- What do you think ?

Example 1: The QTSMALL program

- The (ONLY) example of Mike Cowlishaws books ‚the REXX language' and ‚the NetRexx language'.

- So what's different ?

-

- <BREAK>

So what's different: Labels and Procedures vs Methods

- Rexx and Object Rexx have the concept of Labels

- Denoted by a colon following the label name

- And there is a GO TO statement (named SIGNAL) in Rexx !

So what's different: SIGNAL vs RAISE vs SIGNAL

- Simple SIGNAL in REXX is a GO TO
- Object Rexx also has RAISE for ‚Raising an Exception'
- Which is THROW in Java and SIGNAL in NetRexx!
- … by the rivers of BABYLON!

Jumping FORWARD and BACKWARDS

```
/* example3: simple loops */
F=,abc.def' /* a simple sample file */
N=0
Loop1:
    x = linein( F)
    if length(x) = 0 then signal end_of_file
    n = n + 1
    say x
    signal loop1
End_of_file:
    say n ,lines read'
    exit
```

Jumping *FORWARD and BACKWARDS (classic Rexx)*

```
/* example3: simple loops */
F=,abc.def' /* a simple sample file */
N=0
Loop1:
    x = linein( F)
    if length(x) = 0 then signal end_of_file
    n = n + 1
    say x
    signal loop1
End_of_file:
    say n ,lines read'
    exit
```

```
import Rexx2Nrx.Rexx2RT.RexxFile
class example3 uses RexxFile
properties public static
   FD_F = RexxFile Null
   F = Rexx 'abc.def'
   n = int 0
   xx = Rexx ''
method main(args=String[]) static
arg=Rexx(args) -- program arguments as single string
arg=arg -- avoid NetRexx warning
   F = 'abc.def'
   FD_F = RexxFile.FD(F).access('READ')
   n = 0
   Loop1()
   exit
```

```
method Loop1() static public ;
  /* ... Attention: label: Loop1 is jumped back!   */
  loop label Loop1_again forever
    xx = FD_F.linein()
    if xx.length() = 0 then do
        End_of_file()
        return
    end--if
    n = n + 1
    say n||':'||xx
    iterate Loop1_again
  end--Loop1_again
```
```
method End_of_file() static public ;
   say n 'lines read'
   exit
```

Summary

- Variables are called *Properties* in NetRexx
- *GLOBAL variables* must be defined ahead of their usage (as *STATIC Properties after the CLASS statement*)
- As all variables are LOCAL by default (as in Object Rexx ::Methods and ::Routines !!)
- Avoid Labels whenever possible, use STRUCTURED Statements !!

Standard Program Layout (Declarations)

- OPTIONS BINARY (when applicable)

- IMPORT package-name [.class-name]

- …

- CLASS class-name [USES class-name-list]

- PROPERTIES *PUBLIC* STATIC

- Global ‚Variable' declarations (*visible outside class*)

- PROPERTIES *PRIVATE* STATIC

- Global ;Variable' declarations (*invisible outside class*)

Standard Program Layout (Code)

- METHOD method-name PUBLIC STATIC
- METHOD method-name PRIVATE STATIC
- METHOD method-name (parameter-list) …
  - Where parameterlist is COMMA-delimited LIST of parameter-names (with types and default value)
  - E.g.   Name1, Name2, …   (default Type REXX)
  - Or   Name1=Type1, Name2=Type2, …

Parameter Lists

- Semantically similar to USE ARG name-list in Object-Rexx METHODS.

- Parameter Names *must be different* to class PROPERTIES

- And *ARE INVISIBLE* (cannot be referenced) from out-side of the respective METHOD

- DEFAULT values may be provided for OPTIONAL parameters, e.g:

- METHOD ABC(par1= char[3], par2=int 0) PUBLIC STATIC

Parameter Lists

- Semantically similar to USE ARG name-list in Object-Rexx METHODS.

- Parameter Names *must be different* to class PROPERTIES

- And *ARE INVISIBLE* (cannot be referenced) from out-side of the respective METHOD

- DEFAULT values may be provided for OPTIONAL parameters, e.g:

- METHOD ABC(par1= char[3], par2=int 0) PUBLIC STATIC

Caution

- Notice that *PARSE ARG is ONLY* available for the *MAIN program* (main method)

- Notice that *PULL* and *PARSE PULL* are *NOT* available

- Do not forget the keyword *STATIC* for *methods associated with the CLASS*, and NOT the Objects constructed by the class.

Structured Statements

- Same structured statements than classic REXX

- With a few exceptions/additions:
  - Repetitive DO is called LOOP now
  - Additional key-words:
    - *Label* name
    - *Protect* term
    - *Catch* excption
    - *Finally* instruction-list

- Very well designed by M.F. Cowlishaw …

Structured Statements (2)

- Even PARSE-statement available
- PARSE statement variations no longer used (reserved Variable names like ARG, SOURCE, etc used in turn)
- With same Syntax and Semantics of the TEMPLATES than classic Rexx
- With a small exception:
  - No QUALIFIED Variables (like stems, etc) allowed in NetRexx   (why ?)

Caution (2)

- Notice that up to now we still didn't use any OBJECTS

- But we ARE now able to Write/Generate (procedural) NetRexx Code, at least.

- Object Oriented Programming is another art, not part of this initial tutorial.

-                              …   Good LUCK
